The Automatic Exposure Control Tube Current Modulation Curve as a Candidate Signal for Hypertension, Diabetes, and Chronic Kidney Disease: A Two-Hospital Development and Validation Study Summary Statement.- A curve-shape score derived from the CT scanner's automatic exposure control tube current curve showed a small, mostly non-independent association with hypertension, diabetes, and chronic kidney disease **that did not reach significance after correction for multiple comparisons**, though a residual signal in one principal component survived adjustment for demographic and CT-adiposity covariates.

문장유사율: 25%

Purpose.-To evaluate a prespecified, curve-derived AEC shape score as an incremental predictor of **hypertension (HTN), diabetes mellitus (DM), and chronic kidney disease (CKD)** when added to demographic and CT-adiposity baseline models, using internal development and external validation cohorts.

Outcome Variables (HTN, DM, CKD).-Outcomes were binary diagnoses of hypertension (HTN), diabetes mellitus (DM), and chronic kidney disease (CKD), determined from **the International Classification of Diseases, 10th Revision (ICD-10) diagnostic** history in the same clinical database used for cohort selection, without restriction on diagnosis date relative to the CT scan; this label therefore reflects cumulative, ever-diagnosed status rather than status at the time of scanning.

as coronary artery disease (CAD), hypertension (HTN), diabetes mellitus (DM) and chronic kidney disease (CKD), etiology for chronic liver disease

Discussion To our knowledge, this is the first study to directly examine whether the AEC tube current modulation curve-recorded on essentially every clinically indicated CT scan but studied previously only as a radiation-dose signal-carries information about a patient's cardiometabolic disease status.

[pmc.ncbi.nlm.nih.gov] Dynamic gene expression changes in response to micronutrient, macronutrient, and multiple stress exposures in soybean - PMC

Secondly, to the best of our knowledge, this is the first study to directly examine the relationship between instrumental

Several limitations should be considered when interpreting these results. First, because the classification threshold was fixed at the internal out-of-fold Youden index and applied unchanged to the external cohort, adding the AEC scoreshifted the operating point toward higher sensitivity at the cost of specificity in 11 of 12 comparisons, lowering overall accuracy in 10 of 12-most sharply for chronic kidney disease (external, mean_mAs family: 63.4%→51.3%)-and external calibration was weaker than internal forevery outcome (most markedly chronic kidney disease; TableS4); any future application of this or a similar model at a new site should therefore includesite-specific recalibration rather than applying the raw predicted probabilities reported here.

In summary, the AEC-128 tube current modulation curve-an opportunistic, cost-free byproduct of virtually every clinically acquired CT scan-showed a small, directionally consistent association with hypertension, diabetes, and chronic kidney disease beyond age, sex, height, weight, and CT-derived visceral and subcutaneous fat area, **but this association did not reach statistical significance after correction for multiple comparisons** and was, for most of its components, substantially explained by thesesame covariates.

Appendix S1. Detailed Patient Selection Criteria
Examinations were sequentially excluded from each cohort as follows, matching the order and per-criterion counts shown in Figure 1: (1) missing height or weight in the clinical database; (2) age **younger than 20 years at the time of the** CT examination; (3) height, weight, or BMI identified as an outlier by the interquartile-range (IQR) rule, applied independently to each variable within each cohort (values **below Q1-1.5xIQR or above Q3+1.5xIQR**); (4) missing values for any other clinical variable used
